Digital Menu for Cafes and Restaurant

Introduction

Our website *name_of_website* is used to create digital menu for the restaurants by either clicking the picture of the menu or by zomato and swiggy api(zomato swiggy is part of demo 2 currently only clicking the picture of the menu).

Feature highlights

Most menus of the cafes and restaurants already have these three things highlighted:

1. Item Name
2. Item Price
3. Category (at top category is there then below this item and price is listed) Category is usually highlighted in the Menu with Bold big texts and Category also contains size information (eg. S/M/L or small/medium/large or 8”/10”/12”).

Here one thing to keep in mind is when the category has mentioned the size then the price is also usually given in the same format (if s/m/l then price is 200/300/400 where 200 is s, 300 is m and 400 is l).

We want to make sure our application is making the website it should also add default images (if not provided by the restaurant or cafe) from our default dish image. It should be stored in some database i believe. Also for each item our application should add default description about the dish.

- Description should be very generic and should only mention the main ingredients which is highlight of the dish as it is known. For example in Poha the main ingredient is fluffy poha. Now people do add other things in poha but that’s something which is personal to everyone so these information should be omitted. Our app should include a default description of each dish which is currently sold. Feature name (Default_Descr) (default_image)
- App should have the function for restaurants and cafes to edit the description by themselves if they want. Feature name (Edit_descr)
- App should have option to upload image for the dish by restaurants and cafes.(Edit_Image)
- App should have option for restaurants to add their logo and application should automatically pick color theme based on the logo color theme. How this will be implemented is mentioned later in the document. Feature name (logo_upl) and (colorscheme_upl)

Website Homepage

Homepage of the website is all about what we deliver. Its our page whoever opens it should know what we do. What are some of our highlights and it should be very minimal. We should have a intro about what we do. What we are trying to achieve. Contact details and privacy notice and other default things.

It can be a static page for now. But it should have a login option.

Login feature

Our website will have two kinds of login -

1. Admin login which should be done by us only. We will have our own admin login account and verification. Admin should be able to access any restaurant menu and make edits. They will have all the permission which restaurant login has plus the option to delete things from the menu.
2. Restaurant login. This login will open a page for that particular restaurant and their Menu. The menu screen which opens up after this login will show the restaurant details and a profile and their plan details. They will also have an option to edit their menu, add categories, add dishes, upload images for the dishes. It should basically be a proper web page catered for editing(e_mode) the menu. Restaurants initially will not have option to deleting any item from the menu. Initially only admin can do it.

This is mostly a static page with minimalistic design. Website should be adaptable to laptop size and phone size both.

Admin side web page

Admin page is for logging of us. The company. In future we can add things like employee sign in but for now only admin login is ok.

Admin web page should again be minimalistic. With company logo and name on top.

After that one button for scanning new menu. There should be a menu page with profile details and list of companies. List of companies should have list of all the companies and cafes and restaurants who has use our application to make their web menu.

After clicking on the restaurant name or cafe name from the list it should open in the edit mode (e_mode).

After clicking on the add ne wmenu button it should ask for camera access which will open the back camera and will allow for clicking of the photo. It should not back out after clicking one photo, instead it will keep adding the photos until we click on the done button.

Camera Features

- Should allow multiple photo click.
- Clicked photos should be shown below with X mark on top.
- When click on X mark the image should be removed from the list.
- At the top there should be a done button which will stop the camera app and save the whatever photos we have clicked.
- After clicking is done it should analyze the photo and save the text in categories as described above as item name, item price , category, restaurant name.

Edit page(e_mode)

So edit mode is a very important page. Its the same page which will be used in admin side and client side. But based on who is logged in some features will be omitted.

Because we are primarily making it phone friendly and web friendly so we have to make sure the page adjustment is proper.

Edit mode will be symbol… first of all relationships

Category is parent. Item name and price are child along with description.

Each plate contains item name, price , image and description. Its a tile like thing ok. In edit mode those tiles will have edit option in gryed round button kinda thing on right top corner.. And above that there should be X to remove the particular item also on the left side there will be up and down arrow symbols. These symbols will be used if someone wants to change the orderin of the items. When clicking on edit that tile will be highlighted. Image will have the camera option when clicking on that user can either click the picture or upload from gallery or computer. Item name and description can be edited.

Now like this each row will have tiles of different items. Now items can be moved within the category. There should also be a 3 dot vertical button on the tile.. There they should have option to change the category of the item.

Now category i want to be present in a single row on top… column wise you should be able to change the lining of the category and when category is moved its item child also moved with it.

Now i know we will need some site hosting and database things to store description and images.. Also there should be some data separation between client so for that we can create different tables… also i know website hosting. Honestly not a techy so dont know much about that.
